Explaining rural-urban gap in infant mortality in Kenya

Background: Developing countries have been characterized by high childhood mortality with infant mortality being the largest proportion. Inequalities are observed between different socioeconomic classes and geographical clusters within countries with rural-urban gap in infant mortality rapidly declining. Some countries experience higher infant mortality rates in urban than in rural areas: In Kenya, infants in urban areas experiencing higher risk of dying than those in rural areas since the year 2003. While rural-urban differentials in infant mortality is well documented, turning a blind eye to factors contributing to the rural-urban gap. This study establishes how factors associated with infant mortality contribute to the rural-urban gap. Mosley and Chen analytical framework to study child survival was used to investigate factors that explain the gap between urban and rural infant mortality in Kenya.

Data and Methods: Data from 2014 Kenya Demographic and Health Survey (KDHS) was used. Bivariate and multivariate regression Logistic. Logistic regression was used to determine variables significantly associated with the infant mortality at both bivariate and at multivariate levels. These analysis were carried out for urban and rural data separately. Variables that were significantly associated with infant mortality at multivariate analysis were included in the multivariate decomposition for nonlinear response models - extension of Blinder-Oaxaca decomposition model - to compute their contribution to the urban-rural gap in infant mortality.

Results: Mother's age at birth; sex of the child; size of the child at birth, use of contraceptives; breastfeeding; and ethnicity had a significant positive association with infant mortality. Preceding birth interval and source of drinking water were significant in rural areas but not significant in urban areas. The results shows that 92% of the rural-urban gap in infant mortality was explained by differences in distribution of covariates while 8% was due to differences in coefficients of these covariates. Distribution of source of drinking water; duration of breastfeeding and ethnicity were highest contributor in widening the rural-urban gap in infant mortality by 54%, 23% and 18% respectively. On the other hand, distribution of mother's age at birth and ever use of contraceptives contributed to the reduction of the rural-urban gap in infant mortality by 7% and 2% respectively.
